RECOMMENDATION FOR SPACE  
DATA SYSTEMS STANDARDS

## **ADVANCED ORBITING SYSTEMS, NETWORKS AND DATA LINKS:**

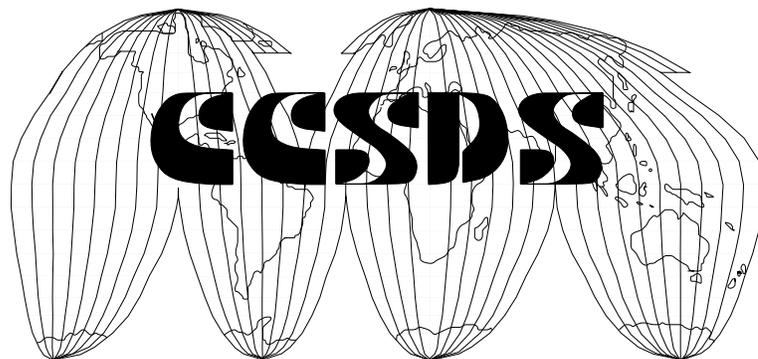

**FORMAL SPECIFICATION OF THE  
VCLC SERVICE AND PROTOCOL**

**ADDENDUM TO CCSDS 701.0-B-2**

**CCSDS 705.3-B-1**

**BLUE BOOK**

May 1994

**AUTHORITY**

Issue:	Blue Book, Issue 1
Date:	May 1994
Location:	Villafranca, Spain

This document has been approved for publication by the Management Council of the Consultative Committee for Space Data Systems (CCSDS) and represents the consensus technical agreement of the participating CCSDS Member Agencies. The procedure for review and authorization of CCSDS Recommendations is detailed in reference [1], and the record of Agency participation in the authorization of this document can be obtained from the CCSDS Secretariat at the address below.

This Recommendation is published and maintained by:

CCSDS Secretariat  
Program Integration Division (Code OI)  
National Aeronautics and Space Administration  
Washington, DC 20546, USA

## STATEMENT OF INTENT

The Consultative Committee for Space Data Systems (CCSDS) is an organization officially established by the management of member space Agencies. The Committee meets periodically to address data systems problems that are common to all participants, and to formulate sound technical solutions to these problems. Inasmuch as participation in the CCSDS is completely voluntary, the results of Committee actions are termed RECOMMENDATIONS and are not considered binding on any Agency.

This RECOMMENDATION is issued by, and represents the consensus of, the CCSDS Plenary body. Agency endorsement of this RECOMMENDATION is entirely voluntary. Endorsement, however, indicates the following understandings:

- o Whenever an Agency establishes a CCSDS-related STANDARD, this STANDARD will be in accord with the relevant RECOMMENDATION. Establishing such a STANDARD does not preclude other provisions which an Agency may develop.
- o Whenever an Agency establishes a CCSDS-related STANDARD, the Agency will provide other CCSDS member Agencies with the following information:
  - The STANDARD itself.
  - The anticipated date of initial operational capability.
  - The anticipated duration of operational service.
- o Specific service arrangements shall be made via memoranda of agreement. Neither this RECOMMENDATION nor any ensuing STANDARD is a substitute for a memorandum of agreement.

No later than five years from its date of issuance, this Recommendation will be reviewed by the CCSDS to determine whether it should: (1) remain in effect without change; (2) be changed to reflect the impact of new technologies, new requirements, or new directions; or, (3) be retired or cancelled.

In those instances when a new version of a RECOMMENDATION is issued, existing CCSDS-related Agency standards and implementations are not negated or deemed to be non-CCSDS compatible. It is the responsibility of each Agency to determine when such standards or implementations are to be modified. Each Agency is, however, strongly encouraged to direct planning for its new standards and implementations towards the later version of the Recommendation.

## FOREWORD

This document, which is a technical Recommendation prepared by the Consultative Committee for Space Data Systems (CCSDS), is intended for use by participating space Agencies in their development of 'Advanced Orbiting Systems'.

This Recommendation, written using the ISO Formal Description Technique LOTOS, contains a formal specification of the VCLC Layer Protocol and Service, described in Natural Language in reference [2]. Annex A contains a set of tests, also written using LOTOS, which specify the required behaviour of the VCLC Layer Protocol and Service under certain control and input conditions.

The Abstract Data Types used within this document are given in full in reference [4], and the rationale behind the production of this formal specification is given in reference [7].

Through the process of normal evolution, it is expected that expansion, deletion, or modification of this document may occur. This Recommendation is therefore subject to CCSDS document management and change control procedures which are defined in reference [1].

## RECOMMENDATION FOR ADVANCED ORBITING SYSTEMS

At time of publication, the active Member and Observer Agencies of the CCSDS were

### Member Agencies

- British National Space Centre (BNSC)/United Kingdom.
- Canadian Space Agency (CSA)/Canada.
- Central Research Institute of Machine Building (TsNIIMash)/Russian Federation.
- Centre National d'Etudes Spatiales (CNES)/France.
- Deutsche Forschungsanstalt für Luft- und Raumfahrt e.V. (DLR)/Germany.
- European Space Agency (ESA)/Europe.
- Instituto Nacional de Pesquisas Espaciais (INPE)/Brazil.
- National Aeronautics and Space Administration (NASA HQ)/USA.
- National Space Development Agency of Japan (NASDA)/Japan.

### Observer Agencies

- Australian Space Office (ASO)/Australia.
- Austrian Space Agency (ASA)/Austria.
- Belgian Science Policy Office (SPO)/Belgium.
- Centro Tecnico Aeroespacial (CTA)/Brazil.
- Chinese Academy of Space Technology (CAST)/China.
- Communications Research Laboratory (CRL)/Japan.
- Danish Space Research Institute (DSRI)/Denmark.
- European Organization for the Exploitation of Meteorological Satellites (EUMETSAT)/Europe.
- European Telecommunications Satellite Organization (EUTELSAT)/Europe.
- Hellenic National Space Committee (HNSC)/Greece.
- Indian Space Research Organization (ISRO)/India.
- Industry Canada/Communications Research Center (CRC)/Canada.
- Institute of Space and Astronautical Science (ISAS)/Japan.
- Institute of Space Research (IKI)/Russian Federation.
- KFKI Research Institute for Particle & Nuclear Physics (KFKI)/Hungary.
- MIKOMTEK: CSIR (CSIR)/Republic of South Africa.
- Ministry of Communications (MOC)/Israel.
- National Oceanic & Atmospheric Administration (NOAA)/USA.
- Swedish Space Corporation (SSC)/Sweden.
- United States Geological Survey (USGS)/USA.

## 1 PURPOSE AND SCOPE

This document provides formal specifications of the Consultative Committee for Space Data Systems (CCSDS) Advanced Orbiting Systems (AOS) VCLC service and protocol<sup>1</sup> using the ISO LOTOS formal description technique (refer to reference [3]). These formal specifications are not intended as replacements for the natural-language specifications provided in the AOS Blue Book (reference [2]), but as unambiguous expressions of those specifications, which may be used to clarify any problem areas.

This document is one of four CCSDS Recommendations that provide LOTOS specifications for the suite of AOS services and protocols (see references [4] through [6]). The relationship between the main AOS Recommendation and the four LOTOS Specifications is shown below; the numbers to the right are the CCSDS document references for the Recommendations containing the LOTOS Specifications.

ADT Library	705.1
Path Service	705.2
Path Protocol	705.2
VCLC Service	705.3
VCLC Protocol	705.3
VCA Service	705.4
VCA Protocol	705.4

A supporting CCSDS Report (reference [7]) contains the rationale, methodology, and approach used to prepare the LOTOS specifications.

These documents are expected to be of use primarily to the technical experts responsible for the design, configuration, and testing of AOS implementations; a basic knowledge of LOTOS is required to understand the formal specifications. Other users of the AOS services should consult the main AOS Recommendation and the companion CCSDS Report (references [2] and [8]).

---

<sup>1</sup>The natural-language specifications for the VCLC service and protocol are contained in the AOS Blue Book, CCSDS 701.0-B-2, reference [2].

## 2 VIRTUAL CHANNEL LINK CONTROL PROTOCOL

```
specification VCLCProtocols [encap, mux, bit, vca, relmux, relbit, man]
    (EncapDataLossEnabled : Bool,
     BitDataLossEnabled : Bool,
     PType : PacketType,
     MuxFill : OctetString,
     BitFill : BitString) : noexit
```

This specification represents the functional requirements of the Virtual Channel Link Control (VCLC) Sublayer protocols, for use in the Space Link Subnetwork (SLS), as described in *Advanced Orbiting Systems, Networks and Data Links: Architectural Specification* (reference [2]).

For the purpose of this LOTOS specification, values are assumed to be available for the parameters PType, MuxFill and BitFill. However, it is not intended that an implementation be constrained to use fixed values in these fields.

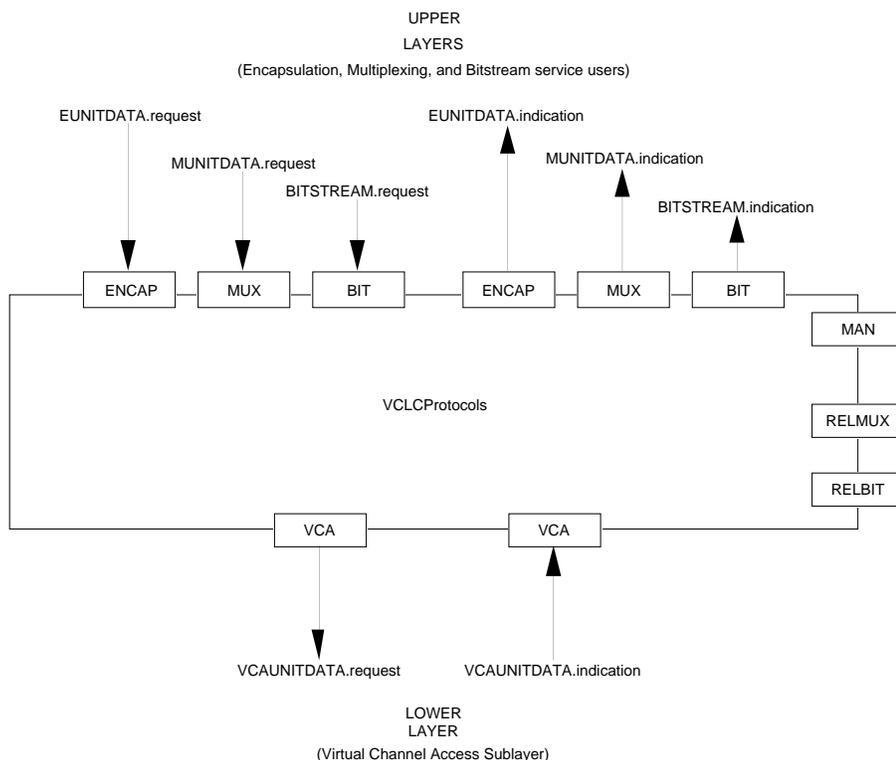

## 2.1 INTRODUCTION

The CCSDS Virtual Channel Link Control service provides transfer of ‘bitstream’ data or octet-aligned ‘packetized’ data across a Virtual Channel. Packetized data may be multiplexed together from a number of sources onto a single Virtual Channel, and may be formatted either as CCSDS Version-1 Packets, or as ISO 8473 Packets which will be encapsulated within CCSDS Version-1 Packets by the VCLC service itself. This concept of ‘encapsulation’ may be extended to other Packet formats in the future; this specification deals only with the encapsulation of ISO 8473. Bitstream data are placed into Virtual Channels dedicated to individual sources; the VCLC service does not provide for the multiplexing of bitstream data.

The Virtual Channel Link Control service uses the Virtual Channel Access service to place the data associated with Virtual Channels into formatted Virtual Channel Data Units.

## 2.2 SPECIFICATION ARCHITECTURE

The LOTOS specification is broken down internally as shown in Figure 2-1. For clarity, each service interface has been shown twice, one instance showing the associated service indication, the other showing the service request. Each of these interfaces is described in more detail below.

**Figure 2-1: Specification Internal Breakdown**

[encap] represents the interface between a VCLC User and an Encapsulation Procedure. A service primitive E\_UNITDATA.request is passed to the VCLC sublayer to request that an E\_SDU be encapsulated and multiplexed into the specified Virtual Channel and sent. The service primitive takes the form of an E\_SDU, VCDU-ID, PCID. For de-Encapsulation, an E\_UNITDATA.indication is employed. An E\_UNITDATA.indication is passed from the VCLC sublayer to indicate the arrival of an E\_SDU.

[enmux] represents the internal VCLC interface between the Encapsulation Procedure and the Multiplexing Procedure. It serves the same purpose as the [mux] interface except that it is not exposed to outside users and remains internal to the VCLC only.

[mux] represents the interface between a Multiplexing Procedure and a VCLC User, through which the Multiplexing Procedure sends and receives M\_SDUs. An M\_UNITDATA.request is used to send data to a Multiplexing Procedure and an M\_UNITDATA.indication is used to send data from a Multiplexing Procedure to the upper layer.

[bit] represents the interface between a Bitstream Procedure and a Bitstream User, through which the Bitstream User sends and receives Bitstream data. The assumption made in this specification is that data is received one bit at a time. This does not constrain an implementation; it is done for flexibility. A BITSTREAM.request is used to send data to a Bitstream Procedure and a BITSTREAM.indication is used to send data from a Bitstream Procedure to a Bitstream User.

[vca] represents the interface between the VCLC and the VCA, through which a Bitstream Procedure or a Multiplexing Procedure sends and receives data. A VCA\_UNITDATA.request is used to send data to the VCA and a VCA\_UNITDATA.indication is received from the VCA.

[relmux] represents an interface to the Multiplexing Procedure, which generates events that the Multiplexing Procedure will respond to by sending a PDU,

and [relbit] represents an interface to the Bitstream Procedure, which generates events that the Bitstream Procedure will respond to by sending a PDU.

[man] represents the interface with management for configuring the proper protocol layers, sub-layers, or procedures. Since the specifications are written to require a separate instantiation for each different stream of data (each Multiplexing Procedure handles only one VCDU-ID, for instance), it is data coming in from this interface that does the instantiation and contains the initial data required.

Note – The [man] gate does not represent a true management interface; functions such as stopping, restarting and interrogating the protocol entities have not been specified. The [man] gate interaction only performs instantiation of protocol entities. The management interface shown here is not intended to constrain an implementation and does not reflect the AOS Blue Book (reference [2]). It is designed to allow a minimal set of management actions to be performed in order to execute the protocol behaviour.

## RECOMMENDATION FOR ADVANCED ORBITING SYSTEMS

ADTs found in the Library:

```
library
  CCSDSPacket, PathID, SecondaryHeaderIndicator, DataLossIndicator,
  ESDULossFlag, MPDU, BPDU, BitstreamDataLossFlag, BitStreamDataPointer,
  VCDUID, VCDULossFlag, Boolean
endlib
```

The ADT, `ServiceType`, is specific to the LOTOS specification of the VCLC and is not intended to constrain any implementation.

```
type      ServiceType is Boolean
sorts     ServiceType
opns      Mux, DeMux           : -> ServiceType
          Encap, DeEncap      : -> ServiceType

             EncapVCDUID,
             EncapPCID,
             True)

        |||
        EncapsulationProcedures [encap, man, enmux]
            (generatedataLossFlags,
             pType)
    )
)

where

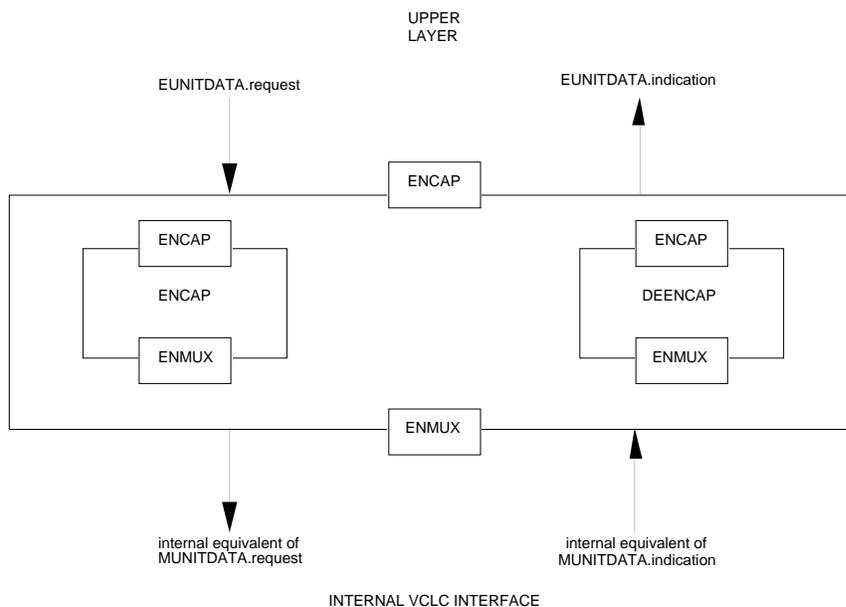

```

This specification provides the functional requirements for the Encapsulation service within the VCLC sublayer, for use in the Space Link Subnetwork (SLS), as described in the AOS Blue Book (reference [2]), Chapter 5.

The Encapsulation service provides transfer of non-CCSDS-structured delimited, octet-aligned Encapsulation SDUs (E\_SDUs) across the Space Link Subnet by encapsulating them within Encapsulation Protocol Data Units (CCSDSPackets). The CCSDSPackets use the CCSDS Packet structure; i.e., a CCSDS Primary Header is appended to the E\_SDU for multiplexing within a virtual channel. The CCSDS Packet structure also incorporates the use of an optional CCSDS Secondary Header but this option will not be included as part of this version of the Encapsulation service specified herein. The service can permit E\_SDUs to have any format, and to be of any length which is an integral number of octets, up to 65,536 octets maximum. In the reverse procedure, a CCSDSPacket may be de-encapsulated by extracting the E\_SDU from the CCSDS Packet Structure. Both aspects are addressed within this specification.

The Packet Channel Identifiers (PCIDs) 2031 to 2046 are reserved for use by the Encapsulation service. The current specification allows only for the encapsulation of ISO 8473 packets. These are assigned the PCID number 2046.

The Encapsulation Service Procedure is specified with two basic interfaces: a VCLC user upper-layer interface (encap) and a lower-layer interface with the Multiplexing Service Procedure (enmux). Refer to Figure 2-2.

**Figure 2-2: Encapsulation Service Interfaces**

## RECOMMENDATION FOR ADVANCED ORBITING SYSTEMS

This specification represents the functional requirements of the Bitstream Procedures protocol, as described in the AOS Blue Book (reference [2]). Refer to Figure 2-3.

**Figure 2-3: Bitstream Procedure Interfaces**

An event at the [relbit] gate signals a release of a B\_PDU. If the event occurs and the B\_PDU is not filled, the Bitstream internal procedure will generate 'Project-specified' Fill Bits to fill the BDZ and send the B\_PDU. This mechanism for setting the fill bits is not intended to constrain an implementation to a similar mechanism.

Once a B\_PDU is filled, it is sent immediately. There is no queuing of B\_PDUs involved in the procedure. Also, it is assumed that bits will be inserted into the B\_PDU bit by bit. However, the method of generating the bitstream data need not be constrained by this; i.e., it may be continuous Bitstream, delimited Bitstream, or individual bits (see AOS Blue Book 5.3.7.5.e).

         FillBS)
    )
  )
)
endproc BPDUCONSTR

```

## RECOMMENDATION FOR ADVANCED ORBITING SYSTEMS

The process BITSTREXTRACT extracts the bitstreams received within B\_PDUs and sends them on as bits to the receiving bitstream user in the order received. It is an independent process and does not use the [relbit] gate as the BPDUCONSTR process does. The UnreportedDataLoss parameter is used to ensure that data loss flags delivered with FillBPDUs are delivered with the next non-Fill bitstream data.

```

process BITSTREXTRACT [bit, vca]
    (VirtualChannel : VCDUID,
     GenerateDataLossFlag : Bool,
     UnreportedDataLoss : Bool): noexit :=

(
    (
        vca ! VirtualChannel
        ? BPDU : OctetString
        ? VCDULossFlag : VCDULossFlag ;

        (
            let BDP : BitstreamDataPointer = GetBitstreamDataPointer
                (GetBPDUHeader
                 (ConvertOSToBPDU(BPDU)))

            in

                (
                    [BDP Eq NoFillDataBDP] ->
                    (
                        [UnreportedDataLoss]->
                        (
                            SENDBIT [bit, vca]
                                (VirtualChannel,
                                 GetBDZ(ConvertOSToBPDU(BPDU)),
                                 GenerateDataLossFlag,
                                 BitstreamDataLost) >>
                            BITSTREXTRACT [bit, vca]
                                (VirtualChannel,
                                 GenerateDataLossFlag,
                                 False)
                        )

                )
            )
        )
    )
)

```

## RECOMMENDATION FOR ADVANCED ORBITING SYSTEMS

The process SENDBIT is used to send each bit in a Bitstream Data Zone (BDZ) to the bitstream user in the order received originally. This means sending the Most Significant Bit (MSB) of the BDZ until none are left.

```
process SENDBIT [bit, vca]
    (VirtualChannel : VCDUID,
     BitsToSend : BitString,
     GenerateDataLossFlag : Bool,
     BitDataLossFlag : BitstreamDataLossFlag ) : exit :=
(
[BitsToSend Ne NullBS] ->
    (
    [GenerateDataLossFlag eq True] ->
        (
            bit ! VirtualChannel
                ! GetMSB(BitsToSend)
                ! BitDataLossFlag;
            SENDBIT [bit, vca]
                (VirtualChannel,
                 RemoveMSB(BitsToSend),
                 GenerateDataLossFlag,
                 BitstreamDataNotLost )
        )
    []
    [GenerateDataLossFlag eq False] ->
        (
            bit ! VirtualChannel
                ! GetMSB(BitsToSend) ;

            SENDBIT [bit, vca]
                (VirtualChannel,
                 RemoveMSB(BitsToSend),
                 GenerateDataLossFlag,
                 BitDataLossFlag )
        )
    )
[]
[BitsToSend eq NullBS] ->
    exit
)

endproc SENDBIT

endproc BITSTREXTRACT

endproc BitStreamProcedures

endproc VCLCProtocols

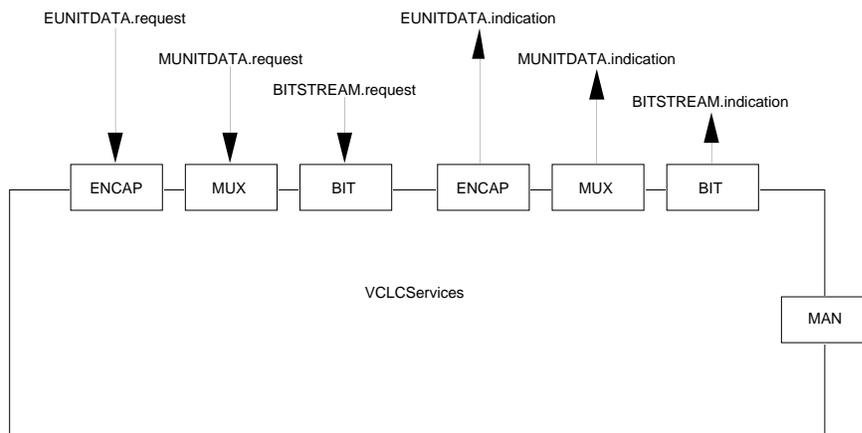

endspec
```

### 3 VIRTUAL CHANNEL LINK CONTROL SERVICE

```
specification VCLCServices [encap, mux, bit, man]
    (EncapDataLossEnabled : Bool,
     BitDataLossEnabled : Bool) : noexit
```

This specification provides the functional requirements for the Encapsulation, Multiplexing, and Bitstream services (those services within the VCLC sublayer) for use in the Space Link Subnetwork (SLS), as described in *Advanced Orbiting Systems, Networks and Data Links: Architectural Specification* (reference [2]), Chapter 5.

The Encapsulation service provides transfer of non-CCSDS-structured delimited, octet-aligned Encapsulation SDUs (E\_SDUs) across the Space Link Subnet by encapsulating them within Encapsulation Protocol Data Units (E\_PDUs) across the Space Link Subnet. The E\_PDUs use the CCSDS Packet structure; i.e., a CCSDS Primary Header is appended to the E\_SDU for multiplexing within a virtual channel. Refer to Figure 3-1.

**Figure 3-1: Encapsulation Service Interfaces**

[encap] represents the interface between a VCLC User and an Encapsulation Procedure. A service primitive E\_UNITDATA.request is passed to the VCLC sublayer to request that an E\_SDU be encapsulated and multiplexed into the specified Virtual Channel and sent. The service primitive takes the form of an E\_SDU, VCID, PCID. For de-Encapsulation, an E\_UNITDATA.indication is employed. An E\_UNITDATA.indication is passed from the VCLC sublayer to indicate the arrival of an E\_SDU.

[mux] represents the interface between a Multiplexing Procedure and a VCLC User, through which the Multiplexing Procedure sends and receives M\_SDUs. An M\_UNITDATA.request is used to send data to a Multiplexing Procedure and an M\_UNITDATA.indication is used to send data from a Multiplexing Procedure to the upper layer.

[bit] represents the interface between a Bitstream Procedure and a Bitstream User, through which the Bitstream User sends and receives Bitstream data. The assumption made in this specification is that data is received one bit at a time. This does not constrain an implementation; it is done for flexibility. A BITSTREAM.request is used to send data to a Bitstream Procedure and a BITSTREAM.indication is used to send data from a Bitstream Procedure to a Bitstream User.

**ANNEX A**

**VCLC PROTOCOL AND SERVICE TESTS**

(THIS ANNEX IS NOT PART OF THE RECOMMENDATION)

**Purpose:**

This Annex details procedures for testing the VCLC protocol and service.

Virtual Channel Link Control Protocol Test 1

Name: Multiplexing.

Description: For each Virtual Channel the Multiplexing Layer constructs M\_PDUs by multiplexing together M\_SDUs and E\_PDUs (both Version-1 CCSDS Packets) [5.3.8.1.2.1]<sup>1</sup>.

Inputs: A string of M\_UNITDATA.requests and E\_PDUs using the same VCDU-ID, but with different PCIDs (APIDs).

Configuration: Management Information concerning M\_PDU size, such that, in conjunction with the above input, several M\_PDUs are generated.

Expected Results: Several VCA\_UNITDATA.requests, all on the same VCDU-ID, containing CCSDS Packets on the above different PCIDs.

---

Virtual Channel Link Control Protocol Test 2

Name: Demultiplexing.

Description: The Multiplexing Layer extracts E\_PDUs and M\_SDUs from M\_PDUs received from the VCA sublayer [5.3.8.1.2.2].

Inputs: A string of VCA\_UNITDATA.indications on the same VCDU-ID as that in the Multiplexing test, containing the VCA\_SDUs generated in the Multiplexing test.

Configuration: No specific configuration data is required.

Expected Results: A string of M\_UNITDATA.indications and E\_PDUs should be passed to the Multiplexing service user and de-Encapsulation Procedures in the reverse of the input to the Multiplexing test.

Virtual Channel Link Control Protocol Test 3

Name: Correct Function of First Header Pointer.

Description: The First Header Pointer in the M\_PDU facilitates delimiting of the variable length SDUs contained within the M\_PDU Packet Zone [5.3.8.2.2.2].

Inputs: Inputs should be provided to test the following conditions:

- 1) M\_UNITDATA.requests such that a Packet Header is split between M\_PDUs A and B, where M\_PDU B contains another complete Packet Header.
- 2) M\_UNITDATA.requests such that an M\_PDU Packet Zone is produced containing only Packet data, i.e., no Header.
- 3) No M\_PDU requests, but a VC\_PDU Release Parameter event such that an M\_PDU is created containing only a Fill Packet.

Configuration: Configuration data should be produced in conjunction with the described inputs above (the only important piece of Management Information is the VCDU/CVCDU Data Zone length).

Expected Results: In case 1), M\_PDU A should have a First Header Pointer pointing to the first Header in the Packet Zone, and M\_PDU B should have an FHP pointing to the complete Packet Header (ignoring the fractional continuation from M\_PDU A). In case 2), the M\_PDU FHP should be set to all ones. In case 3), the M\_PDU FHP should be set to all ones minus one.

Virtual Channel Link Control Protocol Test 4

Name: Correct function of the VC\_PDU release parameter.

Description: Each VCDU-ID has associated with it parameters which define when the VC\_PDU must be released for transmission [5.5.1.2].

Inputs: M\_UNITDATA.requests on VCDU-ID A, constituting input to an M\_PDU of length X, followed by a VC\_PDU Release Parameter event.

Configuration: Management information for VCDU-ID A, such that the required M\_PDU length is much greater than X, and that a VC\_PDU Release Parameter event will occur.

Expected Results: A VCA\_UNITDATA.request should be generated with a filled M\_PDU. The Packet containing the fill data should have a header as follows:

```
Version:           000
Type:             0 or 1
Secondary Header Flag: 0.
APID:            111111111111
Sequence Flags:   11
Sequence Count:   00000000000000
Packet Length:    Number of fill octets - 1
```

Virtual Channel Link Control Protocol Test 5

Name: VCA\_SDU Length Check.

Description: The Channel Access Data Units (CADUs) for a Physical Channel must be of a fixed length over the lifetime of that channel [5.4.10.1]. The Multiplexing Layer must therefore produce VCA\_SDUs which exactly fit the data zone of the VCDU/CVCDU to be transmitted over the Physical Channel in question.

Inputs: A string of M\_UNITDATA.requests such that their overall length exceeds a certain length X.

Configuration: Management information such that the required length of the VCDU/CVCDU data zone is Y, where  $Y < X$ .

Expected Results: At least one VCA\_UNITDATA.request should be produced, with a VCA\_SDU of length Y.

Virtual Channel Link Control Protocol Test 6

Name: Packet Channel ID Checks

Description: The Multiplexing Layer should check the APID (PCID) fields of Packets contained in the M\_PDUs received from the VCA sublayer, generating M\_UNITDATA.indications for those Packets with User APIDs, and passing Packets with APIDs reserved for the Encapsulation service to the de-Encapsulation procedures. Currently, APIDs 0-2031 are User APIDs, 2032-2045 are unassigned reserved APIDs, 2046 is the Encapsulation APID, and 2047 is reserved for Fill Packets.

Inputs: A VCA\_UNITDATA.indication (or string thereof) containing an M\_PDU (or string thereof). Four complete Packets should be contained in the M\_PDU(s), the first with a User APID, the second with the Encapsulation service APID, the third with an unassigned reserved APID, and the last with a Fill Packet APID.

Configuration: No specific configuration is required.

Expected Results: The first Packet should result in an M\_UNITDATA.indication, the second should be passed to the de-Encapsulation procedures, the third should result in an error condition, and the last should be discarded.

Virtual Channel Link Control Protocol Test 7

Name: Non-Version-1 CCSDS Packet.

Description: The Multiplexing Layer Service Data Unit is a Version-1 CCSDS Packet [5.3.6.2.c]. Packets with the Version field set to any other value should not be accepted by the Multiplexing Layer. The Multiplexing Layer should check that Packets are Version-1 whether received from the 'upper layer' (i.e., the Path Layer), or the 'lower layer' (i.e., VCA sublayer). In the first case CCSDS Packets appear in the service primitives; in the second case the Packets are embedded in Multiplexing Layer Protocol Data Units.

Inputs: Two M\_UNITDATA.requests should be generated; the first with a Non-Version-1 version field, the second with a Version-1 version field. These inputs should be followed by an M\_PDU Release event. A VCA\_UNITDATA.indication should be generated where the VCA\_SDU is an M\_PDU containing two short Packets, one of which is a Non-Version-1 CCSDS Packet.

Configuration: No specific configuration is required.

Expected Results: The M\_PDU release event should cause a VCA\_UNITDATA.request to be generated, where the VCA\_SDU contains only the Version-1 CCSDS Packet. The VCA\_UNITDATA.request should be followed by only one Multiplexing indication, with the Packet being the Version-1 CCSDS Packet.

Virtual Channel Link Control Protocol Test 8

Name: Inappropriate Grade Of Service

Description: The Multiplexing Layer is not permitted to operate over Grade 3 Virtual Channels [5.1.4.e].

Inputs: A correctly formatted M\_UNITDATA.request on Virtual Channel X. A correctly formatted VCA\_UNITDATA.indication on Virtual Channel X.

Configuration: Virtual Channel X should be configured as a Grade-3 channel.

Expected Results: Both inputs should result in error conditions.

Note – This test should probably be applied to management rather than the VCLC Protocol; it is included for completeness.

Virtual Channel Link Control Protocol Test 9

Name: Inappropriate VCDU-ID.

Description: Each VCDU-ID is associated with an upper-layer service interface [5.5.1.1.c]. Use of the multiplexing service should not be allowed on a VCDU-ID which is associated with a different service.

Inputs: A correctly formatted M\_UNITDATA.request on VCDU-ID X. A correctly formatted VCA\_UNITDATA.indication on VCDU-ID X.

Configuration: VCDU-ID X should be associated with an upper-layer service other than the Multiplexing service.

Expected Results: Both inputs should result in error conditions.

Note – This test should probably be applied to management rather than the VCLC Protocol; it is included for completeness.

Virtual Channel Link Control Protocol Test 10

Name: Unknown VCDU-ID.

Description: A VCDU-ID forms part of the M\_UNITDATA.request and VCA\_UNITDATA.indication.

Inputs: A correctly formatted M\_UNITDATA.request using VCDU-ID X. A correctly formatted VCA\_UNITDATA.indication using VCDU-ID X.

Configuration: Any management information which excludes VCDU-ID X.

Expected Results: Both inputs should result in error conditions.

Virtual Channel Link Control Protocol Test 11

Name: Inappropriate PCID.

Description: The multiplexing Layer should only accept M\_UNITDATA.requests on Packet Channels which are unreserved; i.e., those Packet Channels between 0 and 2031 inclusive. (Should the Multiplexing Layer permit the passage of Fill Packets? Bearing in mind that the remote Multiplexing Layer will just discard them, no.)

Inputs: M\_UNITDATA.requests on reserved PCIDs.

Configuration: No specific configuration is required.

Expected Results: These inputs should result in error conditions.

Virtual Channel Link Control Protocol Test 13

Name: Encapsulation.

Description: The CCSDS Packet produced by the Encapsulation Layer should have a certain Header format [5.3.8.2.1].

Inputs: Five correctly formatted E\_UNITDATA.requests, with known E\_SDU content.

Configuration: No specific configuration is required.

Expected Results: The resulting M\_SDU should have the following format:

Version:	000
Type:	as per set up information
Secondary Header Flag:	0
APID:	1111111110
Sequence Flags:	11
Sequence Count:	see below
Packet Length:	Number of Octets in E_SDU - 1
User Data:	E_SDU

The five Sequence Counts should be 0, 1, 2, 3, 4.

Virtual Channel Link Control Protocol Test 14

Name: De-Encapsulation

Description: The Encapsulation Layer receives E\_PDUs (Version-1 CCSDS Packets) from the Multiplexing Layer, removes the E\_SDU from the E\_PDU and sends it to the Encapsulation Layer user with an E\_UNITDATA.indication.

Inputs: An E\_PDU from the Multiplexing Layer with known data content.

Configuration: No specific configuration is required.

Expected Results: An E\_UNITDATA.indication with the E\_SDU being identical to the E\_PDU user data.

Virtual Channel Link Control Protocol Test 15

Name: Inappropriate Grade Of Service

Description: The Encapsulation Layer is not permitted to operate over Grade-3 Virtual Channels [5.1.4.e].

Inputs: A correctly formatted E\_UNITDATA.request on Virtual Channel X.

Configuration: Virtual Channel X should be configured as a Grade-3 channel.

Expected Results: This input should result in an error condition.

Note – This test should probably be applied to management rather than the VCLC Protocol; it is included for completeness.

Virtual Channel Link Control Protocol Test 16

Name: Inappropriate VCDU-ID.

Description: Each VCDU-ID is associated with an upper-layer service interface [5.5.1.1.c]. Use of the Encapsulation service should not be allowed on a VCDU-ID which is associated with a different service.

Inputs: A correctly formatted E\_UNITDATA.request on VCDU-ID X.

Configuration: VCDU-ID X should be associated with an upper-layer service other than the Encapsulation service.

Expected Results: This input should result in an error condition.

Note – This test should probably be applied to management rather than the VCLC Protocol; it is included for completeness.

Virtual Channel Link Control Protocol Test 17

Name: Unknown VCDU-ID.

Description: A VCDU-ID forms part of the E\_UNITDATA.request.

Inputs: A correctly formatted E\_UNITDATA.request using VCDU-ID X.

Configuration: Any Management Information which excludes VCDU-ID X.

Expected Results: This input should result in an error condition.

Virtual Channel Link Control Protocol Test 18

Name: Inappropriate PCID.

Description: Currently, only one Packet Channel Identifier (PCID) is reserved for the Encapsulation Service: 2046.

Inputs: E\_UNITDATA.requests on non-Encapsulation PCIDs.

Configuration: No specific configuration is required.

Expected Results: These inputs should result in error conditions.

Virtual Channel Link Control Protocol Test 19

Name: E\_PDU Discontinuities

Description: The Encapsulation Protocol should, if required, generate an E\_SDU Loss Flag derived from the Sequence Count field of the E\_PDU.

Inputs: A sequence of three E\_PDUs, with the Sequence Count fields set to 32, 34 and 35.

Configuration: No specific configuration is required.

Expected Results: Three E\_UNITDATA.indications should be generated, the first with a Data Loss Flag set to false, the second with a Data Loss Flag set to True, and the third with a Data Loss flag set to false.

Virtual Channel Link Control Protocol Test 20

Name: B\_PDU Construction.

Description: The B\_PDU has a certain format [5.3.8.2.3].

Inputs: Eight correctly formatted BITSTREAM.requests, with known bit contents. (NOTE: hippo cannot properly identify a plain '0' as a bit, so the special values Bit0 and Bit1 are being used.)

Configuration: The B\_PDU Construction procedure should be configured to have a Bitstream Data Zone of eight bits, to produce a B\_PDU.

Expected Results: Each resulting B\_PDU should have the following format:

```
Spare:                00
Bitstream Data Pointer: 1111111111111111
Bitstream Data Zone:   01110001 (from input bits)
```

Note – We are currently constraining the Bitstream Data Zone to be an integral number of octets. The AOS Blue Book (reference [2]) does not specify that this must be so, but as the VCDU Data Unit Zone must be an integral number of octets [5.4.9.2.1.3.a], the VCA\_SDU must also. This forces the B\_PDU to be an integral number of octets, forcing the Bitstream Data Zone to be so too.

## RECOMMENDATION FOR ADVANCED ORBITING SYSTEMS

Virtual Channel Link Control Service Test 1

Name: Data Transfer

Description: The Multiplexing Service provides transfer of Version-1 CCSDS Packets across the SLS. These Packets may be passed to the Multiplexing Layer by use of the M\_UNITDATA.request, or they may be passed over an internal VCLC interface from the Encapsulation procedures. The Packets are multiplexed together for transmission over a particular VC, identified by a VCDU-ID.

Inputs: A string of M\_UNITDATA.requests and E\_PDUs, all on the same VCDU-ID, but with the M\_UNITDATA.requests being on several different PCIDs, all having a known data content.

Configuration: No specific configuration is required.

Expected Results: A string of M\_UNITDATA.indications and E\_PDUs, on the same VCDU-ID and PCIDs, with the same known data content as the M\_UNITDATA.requests.

Virtual Channel Link Control Service Test 2

Name: Data Transfer.

Description: The Encapsulation Service provides transfer of non-CCSDS structured delimited, octet aligned data units across the SLS.

Inputs: A string of E\_UNITDATA.requests with known E\_SDU content.

Configuration: No specific configuration is required.

Expected Outputs: A string of E\_UNITDATA.indications with E\_SDU content identical to the original E\_UNITDATA.requests.

Virtual Channel Link Control Service Test 3

Name: Data Transfer

Description: The Bitstream Service is used to transfer Bitstream data across the SLS.

Inputs: A string of BITSTREAM.requests containing known data.

Configuration: No specific configuration is required.

Expected Results: A number of BITSTREAM.requests containing the same data as input, though not necessarily in the same groupings.
